

Figure 4: The **on-path** death of a mutual relative along the shortest path between rulers leads to a substantial decrease in the dyad's kinship connection as measured by inverse shortest path length. A path consists of a series of edges in the royal kinship network. An edge exists between any parent/child, sibling, or married pair of living individuals.

Figure 5: This figure plots the mean war frequency between dyads in the years before and after they experience the death of a relative. Solid dots indicate war frequency before and after an **on-path** death. Hollow dots are conditioned on close family deaths which are not on-path. The dashed line indicates overall average dyadic war frequency. The sample is restricted to dyads which experience only one death within the time horizon. 95% confidence intervals (based on binomial statistics) are indicated by error bars.

Figure 6: Mean war frequency of dyads in the years before and after they experience the **unexpected** death of an on-path relative. The dashed line indicates overall average war frequency. This sample is restricted to dyads which experience only one death within the time horizon. 95% confidence intervals (based on binomial statistics) are indicated by error bars.

Figure 7: The proportion of dyads with at least one country at war (including, but not necessarily with, each other) for the 10 years before and after an on-path death. This sample is restricted to dyads which experience only one on-path death within the time horizon. 95% confidence intervals (based on binomial statistics) are indicated by error bars.
